Final project portfolio instructions

Data Analytics and Statistics with Applications

Purpose: This portfolio is a short, organised presentation of your final project. Choose one of the two project scenarios and present your analysis, interpretation and communication of the results clearly and professionally. It is not a collection of all course activities.

What you need to include

Your portfolio should let a reader understand the question, data, analysis, results, limitations and final communication of your project.

- Completed R analysis file (.R), with clear comments and reproducible code.
- Final analytical report in PDF format, answering the project questions.
- Decision-maker presentation, submitted as PowerPoint or PDF.
- A short README, introduction or portfolio page explaining the project and linking the files.

Accepted portfolio formats

Choose the format that best fits your technical comfort level. GitHub is encouraged, but it is not required.

Portfolio format	When to choose it	What to include
GitHub	For students comfortable with Git/GitHub.	README, R file, report, presentation, selected figures.
Drive or OneDrive folder	A simple and fully acceptable option.	Organised folder with the R file, report, presentation, and README.
GitHub Pages or similar	Optional advanced presentation route.	A simple webpage presenting the project and linking to files and key results.
Canva, Wix, or Adobe Portfolio	Optional visual presentation route.	A shared page presenting the project, with links to the R file, report and presentation.
Organised folder or ZIP	Minimum valid fallback.	R file, report, presentation and a short README or introduction.

Recommended structure

1. Project title and scenario. State which final project scenario you chose and briefly describe the problem.

2. Research question. Explain what you investigated.

3. Data. Describe the source, main variables and important data-quality or ethical considerations.

4. Analysis workflow. Summarise the main steps in R: preparation, exploratory analysis, relationships and statistical modelling.

5. Key results. Show the most important statistics, plots and model results. Do not reproduce all R output.

6. Interpretation and limitations. Explain what the results mean, how certain the conclusions are, and what cannot be concluded. Include causality, confounding and practical importance where relevant.

7. Decision-maker presentation. Include or link to your short non-specialist presentation of the main findings, practical meaning, uncertainty and limitations.

8. Reflection. Briefly explain what you learned, what was difficult and what you would improve with more time.

Minimum acceptable version

If you do not want to create an online portfolio, submit one clearly organised folder or ZIP file containing the completed R analysis file, final analytical report, decision-maker presentation, and a short README or introduction. Submitting only the report or only the R file is not enough.

Practical advice

- Use simple file names and organise your files so the structure is immediately clear.
- Run your R script from a clean session before submission and check that it works from beginning to end.
- Keep the portfolio selective. Show results that help explain the analysis rather than every piece of output.
- Make sure figures and tables have clear titles or captions.
- If you use GitHub, include a README.md file at the top of the repository.
- If you use Drive or OneDrive, check that the sharing link allows the instructor to view the files.
